

Projectile Management System.

Creating Projectiles :

To create a new projectile make a [PrefabVariant](#) form the [Projectile_Template](#).

Make your projectile mesh or effect a child of the [Effects_Mesh](#) transform.

Make the effects you want to play when the projectile hits a target a child of the [Effects_Impact](#) transform

There are options for :

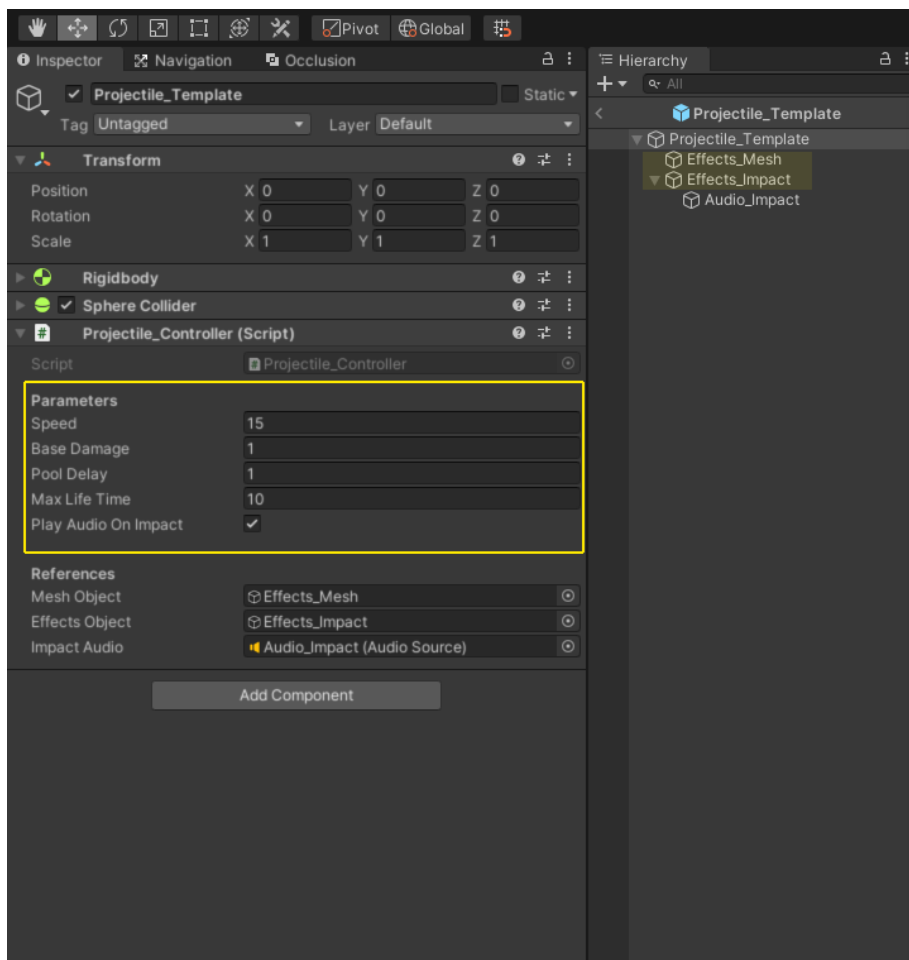

[Speed](#) : projectile movement speed,

[Base Damage](#) : can be multiplied when fired by a [_damageMultiplier](#) parameter,

[Pool Delay](#) : the time to wait for the explosion effects to play out before pooling,

[Max Life Time](#) : if nothing is hit how, long till the projectile is pooled,

[Play audio on impact](#) : yes or no.

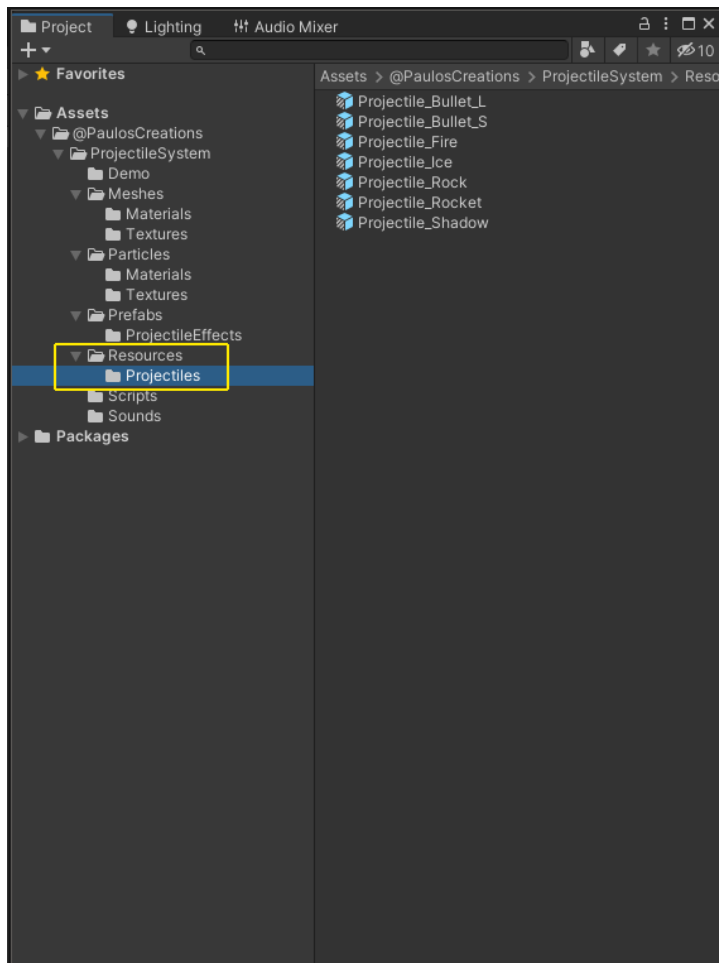

Storing Projectiles:

Created projectiles should be placed in a folder inside a Resource folder in your project.

The name of the folder is used to get the projectiles by the Projectile Manager.

You can make different folders for different levels if you want to.

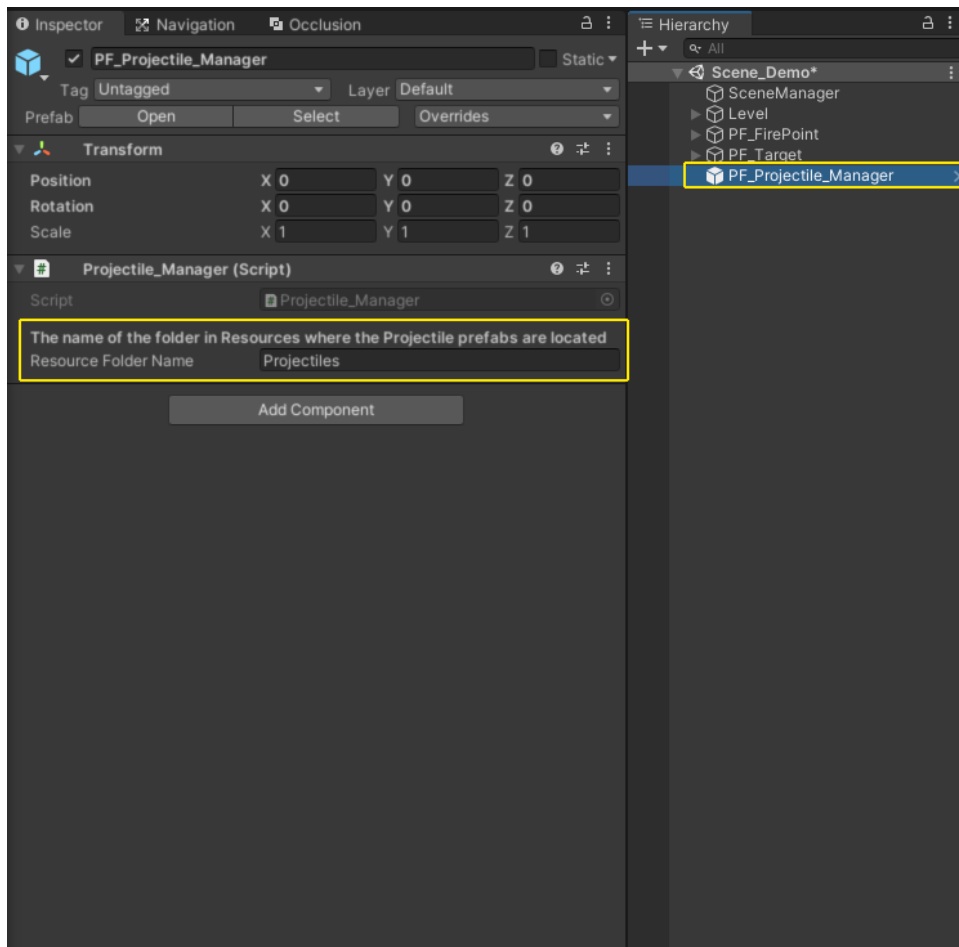

Projectile Manager:

Drag the [PF_Projectile_Manager](#) into each scene you want to be able to fire projectiles in.

The [Resource Folder Name](#) should be the name of the folder you placed the projectile prefabs in.

This can be a different folder for each level, but can not be changed at runtime.

Fire Projectile:

From any script in the level you can fire a Projectile by calling one of these Functions.

To access the manager include the Namespace : [using Paulos.Projectiles](#)

To call the functions that fires a projectile :

[Projectile_Manager._Instance.FireProjectileForward\(ProjectileName, the Transform you fire from\);](#)

There are 4 ways of projectile movement : [straight forward](#), [aimed at target](#), [directional](#) and [homing](#).

All with several parameter options.

(including a damage multiplier and a reference to the transform that fired the projectile.)

```

//fire in a direction with projectile name and startpoint
public void FireProjectileDirectional(string _projectileName, Transform _startPointTF, Vector3 _moveDirection)[]

//fire in a direction with projectile name and startpoint and custom damage to apply
public void FireProjectileDirectional(string _projectileName, Transform _startPointTF, Vector3 _moveDirection, float _damageMultiplier)[]

//fire forward with projectile name and startpoint
public void FireProjectileForward(string _projectileName, Transform _startPointTF)[]

//fire forward with projectile name and startpoint and custom damage to apply
public void FireProjectileForward(string _projectileName, Transform _startPointTF, float _damageMultiplier)[]

//fire homing with projectile name, startpoint, and target
public void FireProjectileHoming(string _projectileName, Transform _startPointTF, Transform _targetTF)[]

//fire homing with projectile name, startpoint, target and custom damage to apply
public void FireProjectileHoming(string _projectileName, Transform _startPointTF, Transform _targetTF, float _damageMultiplier)[]

//fire aimed with projectile name, startpoint and target
public void FireProjectileAimed(string _projectileName, Transform _startPointTF, Transform _targetTF)[]

//fire aimed with projectile name, startpoint, target and custom damage to apply
public void FireProjectileAimed(string _projectileName, Transform _startPointTF, Transform _targetTF, float _damageMultiplier)[]

//with reference to the attacker passed to the target
//fire in a direction with projectile name and startpoint
public void FireProjectileDirectional(string _projectileName, Transform _startPointTF, Vector3 _moveDirection, Transform _attacker)[]

//fire in a direction with projectile name and startpoint and custom damage to apply
public void FireProjectileDirectional(string _projectileName, Transform _startPointTF, Vector3 _moveDirection, Transform _attacker, float _damageMultiplier)[]

//fire forward with projectile name and startpoint
public void FireProjectileForward(string _projectileName, Transform _startPointTF, Transform _attacker)[]

//fire forward with projectile name and startpoint and custom damage to apply
public void FireProjectileForward(string _projectileName, Transform _startPointTF, Transform _attacker, float _damageMultiplier)[]

//fire homing with projectile name, startpoint, and target
public void FireProjectileHoming(string _projectileName, Transform _startPointTF, Transform _targetTF, Transform _attacker)[]

//fire homing with projectile name, startpoint, target and custom damage to apply
public void FireProjectileHoming(string _projectileName, Transform _startPointTF, Transform _targetTF, Transform _attacker, float _damageMultiplier)[]

//fire aimed with projectile name, startpoint and target
public void FireProjectileAimed(string _projectileName, Transform _startPointTF, Transform _targetTF, Transform _attacker)[]

//fire aimed with projectile name, startpoint, target and custom damage to apply
public void FireProjectileAimed(string _projectileName, Transform _startPointTF, Transform _targetTF, Transform _attacker, float _damageMultiplier)[]

```

Hitting the target:

Place the **Projectile_Impact** script on the targets you want to be effected/damaged by the projectiles.

If the target has a **RigidBody** component attached to it,

the script should be placed on the **Transform** that RigidBody component is on.

Otherwise the script should be placed on the **Transform** that the **Collision** is on.

On a projectile hitting a target the **OnProjectileImpact** Event will be called passing the **damage** and optional **transform** that fired the projectile.

From here you can execute the functions from any script you want to be called when the target is hit.
